Abstract: This study focused on the effects of addition of xanthan gum (XG) on the rheological properties of soy protein isolate (SPI) solution. Three types of tests (steady shear test, strain sweep test, and frequency sweep test) were performed to figure out the influences of shear rate on the viscosity of the SPI-XG hybrid system, the effects of strain variable on the storage modulus of the hybrid system, and the effects of frequency on both the storage modulus and the loss modulus of the hybrid system, respectively. SPI-XG hybrid system showed more obvious shear-thinning properties compared to pure SPI and pure XG solution. Meanwhile, it was found that the critical point of hybrid system was highly related to the XG concentration. XG can postpone the critical point strain amplitude to a higher value, and the addition of XG can enhance the strain resistance of hybrid system. The concentration of XG influenced the viscoelastic frequency dependence of the hybrid system significantly and complicatedly. After the addition of XG, the correlation between G′ and frequency changed from negative to positive.

1 Introduction

Proteins are large bio-molecules, consisting of one or more long chains of amino acid-residues. Proteins perform a vast array of functions within organisms, including catalysing metabolic reactions, DNA replication, responding to stimuli, and transporting molecules from one location to another[1]. Participating in all organisms’ essential reaction, protein is an important component of the human body’s cells. In general, the proportion of protein in the total dry mass of the human body is approximately 18%, which is an element close to human life[2]. Soy protein isolate (SPI) is a kind of protein food additive that can be obtained from low-temperature desolventizing soybean meal as raw materials[3]. SPI has many functional properties of emulsifying, foaming, gelation, and film forming.[4]. Moreover, SPI is also abundant in nutrients and has the features of reducing serum cholesterol and preventing cardiopathy and cerebrovascular disease. The demand of SPI is continuously growing because of its nutritional and functional properties.[5,6] Therefore, SPI, as a kind of functional ingredient, has been developing extensively in food industry. In addition, some specific properties of SPI can be modified with the appropriate addition of other materials.

Polysaccharide is composed of multiple monosaccharide molecules, which is a kind of carbohydrate. They range in structure from linear to highly branched[7]. Examples include storage polysaccharides such as starch and glycogen, and structural polysaccharides such as cellulose and chitin. Gum, such as pectin and gelatin, is a kind of polysaccharide, which is extensively applied in food industry[8]. Xanthan Gum (XG), the study subject in this article, is single spore microbe polysaccharide, which is able to dissolve not only in cold water but also in hot water[9-11]. The solution of XG is neutral. XG is a complex polysaccharide fermented using Xanthomonas campestris, which is mainly produced by corn starch as substrate[12,13]. XG can act as emulsifier, stabilizer and gel thickener in the food industry due to the functional properties, such as emulsifying property, thermal stability, thickening property.[14,15] Compared with the common edible gums of pectin and gelatin, the XG has more stable property and is more predominant in food processing[16,17].

Protein and polysaccharide play an important role in manufactured foods due to their unique functional and textural properties. When protein and polysaccharide are hydride, it is expected that their behaviors are affected by each other[18]. It was found that the charged polysaccharides readily interact with other macromolecules such as lipid and protein[19]. The bio-macromolecules interact with each other through weak interactions such as electrostatic forces, Van der Waal forces, hydrogen bonds, and hydrophobic systems[20]. When protein
mixed with polysaccharide, a hybrid system can be gained only in some particular circumstances, such as given temperature, proper pH, and appropriate ionic strength. Protein-polysaccharide hybrid system has more powerful functional properties compared to pure protein or pure polysaccharide because of the interaction between protein and polysaccharide.

In food industry, the interaction of protein and polysaccharide always determined the texture and acceptability of product. For example, polysaccharide is always applied into dairy products as stabilizer and gel thickener to improve the rheological property of emulsion. It forms reticular structure in the space that can prevent delamination caused by phase separation and the gravity. Protein molecule is beneficial to form the emulsion of good stability through the action of static electricity. The interaction of protein and polysaccharide is widely used in increasing the shelf life of milk and improving the products’ quality[21]. Most proteins in food can occur adsorption with anionic polysaccharide by electrostatic and form a new complex with more excellent characteristics. In this way, the rheological property and adsorption behavior of protein will be improved and the stability of the solution will also be developed. The process that polysaccharide makes protein remain stable is a completed progress. In some circumstance, protein can interact with polysaccharide through static electricity force, hydrophobic force and hydrogen bond. Only in some specific concentration and polymer ratio, a kind of highly homogeneous mixture can be obtained. According to the report, the interaction of protein and polysaccharide has obvious effects on the stability of emulsion.

The rheological property is a type of quantitative relationships between stress and strain on the object suffered from external forces, which is related to the nature and internal structures of object. As a result, it becomes especially important to study the rheological properties of protein-polysaccharide hybrid system. The rheological property study can provide abundant useful information, such as the interaction between food components, the selection standard of different additives, and the processing problems in many aspects such as transportation[22]. Usually, the rheological properties of protein-polysaccharide hybrid system are not simply an addition of parameters of two components.

This article mainly studies on the influence of the addition of XG on the rheological properties of soy protein solution. The formation of hybrid solution of SPI and XG is greatly affected by the temperature and the chemical factors, such as ionic strength, pH of aqueous phase, and physical factors (high shear). Through steady shear test, strain sweep test and frequency sweep test, the article is devoted to study on the effect of shear rate on the viscosity (η) of the SPI-XG hybrid system, the effect of strain variable on the storage modulus (G′) of the SPI-XG hybrid system, and the effect of frequency on both the storage modulus (G′) and the loss modulus (G″) of the SPI-XG hybrid system, respectively.

2 Materials and methods

2.1 Materials

Commercial SPI (S30914, BR grade, pH=7.0±0.5, protein content ≥90.0%, moisture content ≤7.0%) was obtained from Shanghai Yuanye Bio-Technology Co. Ltd. (Shanghai, China). XG (G810381, USP grade) was obtained from Shanghai Macklin Biochemical Co. Ltd. (Shanghai, China). The above materials were used in experiment without any processing.

2.2 Sample preparation

Six grams SPI powder and 0.25 g XG powder were completely dissolved in 100 mL deionized water by magnetic stirring at 600 r/min for 20 min, in which the concentration of SPI dispersion liquid and XG solution were 6% and 0.25%. After that, 9 g SPI powder was dissolved in 100 mL deionized water using the magnetic stirrer (600 r/min) for 20 min. The third stage was to dissolve 0.075 g, 0.225 g and 0.375 g XG powder in 50 mL deionized water respectively, and the solutions were stirred at 600 r/min for 20 min. Two kinds of solutions (which are formed in the second and third stage) were mixed and continue stirred for 20 min to completely mix. Then, three kinds of solution have been prepared: 6% SPI-0.05% XG hybrid system; 6% SPI-0.15% XG hybrid system; 6% SPI-0.25% XG hybrid system. All the samples were performed at room temperature (25°C) and stored in the refrigerator at 4°C overnight for further rheological test.

Before testing, the overnight samples needed to be stirred for 5 min on magnetic stirrer to ensure the homogeneity of the samples.

2.3 Methods

2.3.1 Rheological test

The tests of rheological properties were all conducted on AR2000ex rheometer (TA Instruments Company, USA) and the temperature control was in charged by Peltier system. In the experiment, the aluminum parallel plate geometry (40 mm diameter) was selected, and the gap between the geometry and Peltier plate was 1000 μm. Before all the tests, samples need to be equilibrated on the rheometer for 2 min to eliminate the impact of sample loading on the final result.

The characterization of rheological properties consisted of three tests: steady shear test, strain sweep test, and frequency sweep test. Each test was performed in a continuous temperature changing process.

2.3.1.1 Steady shear test

The temperature was set at 25°C, and the shear rate needed to be controlled in the range of 1-100 s⁻¹. In food industry, some common operating frequencies are as follows: 1-100 s⁻¹ for extrusion; 1-1000 s⁻¹ for pipe flow; 10-1000 s⁻¹ for stirring[23]. The controlled range of shear rate in this test was accordance with the above shear rate.

Temperature-changing test: in the test of influence of temperature on the rheological properties of the hybrid system, temperatures of the test were controlled in three gradients at 25°C, 45°C and 65°C, and the shear rate is also set in the range of 1-100 s⁻¹.

2.3.1.2 Strain sweep test

In strain sweep test, the strain amplitude was set in the range of 0.1%-10.0%, which was within the vibration strength during food processing and transportation. Temperature was set at 25°C, 45°C and 65°C, respectively. And the oscillatory frequency was 1 Hz. The value of storage modulus (G′) and the loss modulus (G″) were recorded during the strain sweep test every 10 point per decade. Linear Viscoelastic Region (LVR) of each sample in each temperature was determined for the following dynamic rheological test. When the strain amplitude applied in the LVR, the change of strain amplitude do not impact the detected values of G′ and G″.

2.3.1.3 Frequency sweep test

Frequency sweep test conducted after strain sweep test, since the oscillatory strain amplitude of this test have to be within the LVR of each sample, which obtained from the strain sweep test. The temperature of experiment was controlled at 25°C, and the giving frequency was set during 0.1 Hz to 1 Hz taking 10 points per logarithmical decades. The setting strain was controlled at
0.2%, and both the storage modulus ($G'$) and the loss modulus ($G''$) of SPI-XG hybrid system was detected and recorded as a function of frequency.

The frequency dependence of both storage modulus ($G'$) and loss modulus ($G''$) of SPI-XG hybrid system could be fitted by the Power Law Model: \[G' = K' \cdot f^n\]
\[G'' = K'' \cdot f^{n''}\]
where, $K'$ and $K''$ are the power law constant, Pa·s$^{-1}$/rad$^n$; $n'$ and $n''$ are frequency indexes, which is to reflect the viscoelasticity frequency dependence of sample.$^{[25,26]}$

In order to investigate the effect of temperature on the frequency dependence of the hybrid system, the temperature was controlled in three gradients at 25°C, 45°C and 65°C.

2.3.2 Statistical analysis

The experimental data of rheological test can be obtained directly from software supporting with rheometer on computer. All the above experiments were repeated three times, and the average values were shown in tables and figures. Regressions and corresponding equations were processed by SPSS statistical package (SPSS 16.0, IBM Corporation, USA).

3 Results and discussion

3.1 Steady shear test

The effect of shear rate on the viscosity ($\eta$) of the SPI-XG hybrid system at 25°C is shown in Figure 1. It can be observed from the diagram that within the shear rate range of steady shear test (1-100 s$^{-1}$), the pure XG sample shows the lowest viscosity, following by the pure SPI samples. With the increase of the concentration of XG, the viscosity of the hybrid system increased. Among all the samples, either the SPI-XG hybrid system or the pure SPI/XG samples, their apparent viscosities increased with the applying shear rate decreasing. This phenomenon indicated that all samples showed obvious shear-thinning properties. The shear-thinning property was related to the molecule re-arrangement of shear direction as a result of molecular structure.$^{[27,28]}$ At the beginning, the shear rate was in low velocity zone and the change of molecular structure due to shearing was not obvious. In this shear rate zone, in order to maintain the structure, inner-molecular forces provided a cohesive trend to resist the external force from changing the molecular structure. As a result, the viscosity of SPI-XG hybrid system remained a higher extent in the case of lower shear rate. With the shear rate increasing, the inner-molecular force was not enough to resist the structure change. The original intact molecule was forced to unfold, which greatly reduced the anti-shearing behaviors of molecule, so that apparent viscosity fell with it. Moreover, it can be seen from the diagram, the viscosity of SPI-XG hybrid system (70 Pas, when $\gamma$=1 s$^{-1}$) was much higher than that of pure XG (6 Pas, when $\gamma$=1 s$^{-1}$) or pure SPI samples (8 Pas, when $\gamma$=1 s$^{-1}$), which means SPI and XG have obvious synergistic effect. That may be due to the increasing relative density of protein polymer as a result of adding XG in it.

The effect of temperature on the shear rate curve of the SPI (6%)-XG (0.25%) hybrid system is depicted in Figure 2. According to the graph, within the shear rate range of steady shear test (1-100 s$^{-1}$), the higher the temperature was, the lower the viscosity of the sample was. That is to say, the increasing temperature can declined the viscosity of the samples. At the same temperature, the apparent viscosity of the sample decreased with the increasing shear rate. Lower temperature led the SPI-XG hybrid system to more obvious shear-thinning characteristics.

3.2 Strain sweep test

The effects of strain amplitude on the storage modulus ($G'$) of the SPI-XG hybrid system is presented in Figure 3. It can be seen from the diagram, within the strain range of strain sweep test (0.1%-10.0%), the pure XG (0.25%) sample performed the lowest storage modulus (approx. 40 Pa), following by the pure SPI (6%) sample (approx. 100 Pa). With the increase of the concentration of XG, the $G'$ value of the hybrid system increased significantly (6% SPI+0.25% XG, approx. 700 Pa). At the beginning, the storage modulus curve of the hybrid system showed a platform and began to decline with the strain amplitude increased gradually. We simply defined the data point that $G'$ declined to 95% of $G'_{ave}$ (platform average $G'$ value) as the critical point of “LVR”.$^{[29,30]}$ It can be observed from the diagram that with the concentration of XG increasing, the imposed strain amplitude of the LVR critical point rose gradually, which means XG shows the trend to resist the influence of external strain on the elasticity of SPI-XG hybrid system.

Figure 4 shows the effects of temperature on the storage modulus ($G'$) as a function of strain of the SPI-XG hybrid system. According to the graph, within the strain range of strain sweeping test (0.1%-10.0%), the storage modulus of the SPI-XG hybrid system decreased significantly with the increase of temperature. The diagram also revealed that the imposed strain on the LVR
critical point did not change obviously. Hence, the influence of temperature on the elasticity of SPI-XG hybrid system for resistance to the external strain is inconspicuous.

Figure 3  Effects of strain on the storage modulus ($G'$) of the SPI-XG hybrid system ($t=25{\degree}C$)

Figure 4  Effects of temperature on storage modulus ($G'$) of the SPI-XG hybrid system as a function of strain

3.3 Frequency sweep test

The effects of frequency on both storage modulus ($G'$) and loss modulus ($G''$) of the SPI-XG hybrid system in the case of 0.2% strain at 25{\degree}C is shown in Figure 5. Within the applied frequency range (0.1-1.0 Hz), the value of $G'$ and $G''$ of all samples increased with the increase of frequency, except for the pure SPI sample. This phenomenon indicated that the addition of XG dominated the frequency dependence performance of SPI-XG hybrid system. At the same frequency, the $G'$ and $G''$ of pure XG were the lowest, following by that of pure SPI. With the increase of the concentration of XG, the value of $G'$ and $G''$ of the hybrid system also increased, which means the addition of XG enhances both elasticity characteristic and viscosity characteristic of SPI-XG hybrid system.

The data obtained by frequency sweep test can be regressed by the Power Law Model very well ($R^2>$0.96). The parameters of the regression are listed in Table 1. The values of $K'$ and $K''$ rose sharply because of the increasing concentration of XG, which proved that both the viscosity and elasticity of the SPI-XG hybrid system were strengthen by the addition of XG. The values of $K'$ of SPI-XG hybrid system were much higher than the value of $K''$ that indicated hybrid system was more elastic. The value of $n'$ expressed the frequency dependence extent of the elasticity of samples. The hybrid system showed obvious larger values of $n'$ than that of pure XG or pure SPI. This trend indicated that the elastic properties of SPI-XG hybrid system were more frequency dependent than that of pure XG or pure SPI. However, the values of $n''$ in this three hybrid systems did not change significantly with the change of concentration of XG. That means concentration of XG in the hybrid system scarcely has any effect on the frequency dependence of elastic properties. The value of $n''$ expressed the frequency dependence extent of the viscosity of samples. The value of $n''$ of SPI-XG hybrid system decreased slightly with the addition of XG. That means the addition of XG reduces the frequency dependence of viscous properties, making the SPI-XG hybrid system less sensitive to frequency.

The effects of temperature on the frequency sweeping spectrums of SPI-XG hybrid system is shown in Figure 6. It can be seen from the diagram, within the frequency range applied (0.1-1.0 Hz), the value of $G'$ and $G''$ of SPI-XG hybrid system decreased significantly with the temperature increasing, while the trend of the curves did not change a lot.

The parameters of the regression are shown in Table 2. The values of $K'$ decreased from 734.65 (25{\degree}C) to 273.50 (65{\degree}C) and
In a word, the rheological properties of SPI-XG hybrid system become more sensitive to frequency when the system expose to high temperature. However, the molecular level interaction between SPI and XG needs to be investigated in further study.

In strain sweep test, the LVR critical point of SPI-XG hybrid system was determined. It was found that the critical point of hybrid system was highly related to the XG concentration. XG can postpone the critical point strain amplitude to a higher value. This phenomenon indicated that the addition of XG enhanced the strain resistance of hybrid system. Temperature was not demonstrated to have effects on the strain resistance of the hybrid system.

In frequency sweep test, the addition of XG significantly changed the frequency dependence, especially the trend of \( G' \). The \( G' \) value of pure SPI solution showed a negative correlation with frequency. However, after the addition of XG, the correlation between \( G' \) and frequency became positive. As to the viscosity characteristic, the trend of \( G'' \) as a function of frequency flattened out with the addition of XG. It was demonstrated that the addition of XG influenced the viscoelastic frequency dependence of the hybrid system significantly and complicatedly. Temperature acted a much ordinary role on affecting the frequency dependence properties of hybrid system. The value of \( G' \) and \( G'' \) both showed that less frequency dependency was changed with temperature rising. That meant the sensitivity on frequency of both elastic and viscous characteristic of hybrid system had a negative correlation with temperature.
